## PROBLEM STATEMENT

Dementia often causes individuals to forget important information such as who they are, where they are, or what they should be doing, which can reduce independence and increase caregiver burden.

Many existing solutions focus only on monitoring rather than providing real-time support. There is a need for an accessible system that helps users stay oriented while keeping caregivers informed of potential safety concerns.

## CHALLENGES

- Ensuring accurate and trustworthy AI responses
- Protecting sensitive health and location data
- Maintaining reliable cloud connectivity and real-time updates
- Designing a simple interface for users with cognitive decline

## SOLUTION

reMIND is a wearable AI companion designed to support individuals living with dementia through voice-based interaction and personalized reminders.

The system uses a friendly AI persona, Remi, to answer questions, provide orientation cues, and deliver daily reminders.

By combining contextual data such as time, location, and user history, the system helps users maintain independence while ensuring caregivers remain informed of important events.

## TECHNOLOGIES

## IMPLEMENTATION

The reMIND system follows a three-tier architecture consisting of a wearable patient interface, cloud infrastructure, and caregiver application.

A watchOS application built with Swift captures voice input, health metrics, and location data. This information is processed through an Azure-based backend using REST and WebSocket APIs.

AI services provide speech recognition and contextual responses. Caregiver applications access real-time updates through the system API.
